What's recursion

- A powerful problem solving technique
- A special case of divide-and-conquer technique
 - Sub-problems have the exact type of the original type, with smaller size
- A function of accomplishing a task by invoking itself

How to construct recursive solution?

Four questions for constructing recursive solutions

- How can you define the problem in terms of a smaller problem of the same type?
- How does each recursive call diminish the size of the problem?
- What instance of the problem can serve as the base case?
- As the problem size diminishes, will you reach this base case?

■ Problem

- Compute the factorial of an integer n

■ An iterative definition of factorial(n)

$$\text{factorial}(n) = n * (n-1) * (n-2) * \dots * 1$$

for any integer $n > 0$

$$\text{factorial}(0) = 1$$

■ A recursive definition of factorial(n)

$$\begin{aligned} \text{factorial}(n) &= 1 && \text{if } n = 0 \\ &= n * \text{factorial}(n-1) && \text{if } n > 0 \end{aligned}$$

- Label each recursive call in the function body
- Represent each call to the function by a new box containing local environment of the function.
 - parameters
 - local variables
 - placeholder for return value
 - the value of the function itself
- Draw an arrow from the box that makes the call to the newly created box, and label each arrow
- Start executing the function body corresponding to new created box
- On exiting the function, cross off the current box and follow its arrow back to the box that called the function

STL Sorting
Algorithms

■ Costs

- Recursion: calling the same function over and over
- Iteration: 'jumps back' to the beginning of the loop.

■ Iteration is more efficient

- A function call is often more expensive than a jump.
 - Space: Every function call may require space for parameters and local variables. A recursive algorithm may need space proportional to the number of nested calls.
 - Time: Allocating and later releasing local memory, copying values into the local memory for the parameters, branching to/returning from the function.
- “Clever” compilers may produce machine code that incurs minimal or no overhead for recursion.
- Most recursive solution can be rewritten as iteration

- Recursion is a technique that solves a problem by solving smaller problems of the same type
- When constructing a recursive solution, keep the following 4 questions in mind
 - How to define the problem in terms of a smaller problem of the same type?
 - How does each recursive call diminish the size of the problem?
 - What instance of the problem can serve as the base case(s)?
 - As the problem size diminishes, will you reach this base case?
- You can use the box method to trace the actions of a recursive functions. Each box represents a activation record.

STL Sorting
Algorithms

- Recursion allow you to solve problems – such as the Towers of Hanoi – whose iterative solution are difficult to conceptualize. Even the most complex problems often have straightforward recursive solutions. Such solutions can be easier to understand, describe, and implement than iterative solutions.
- Some recursive solutions are much less efficient than a corresponding iterative solution due to their inherently inefficient algorithms and the overhead of function calls.
- If you can easily, clearly, and efficiently solve a problem by using iteration, you should do so.
