

Representing Lines (4)

- *L*(*t*) lies fraction *t* of the way between *C* and *B* when *t* lies between 0 and 1.
- When t = 1/2 the point L(0.5) is the midpoint between C and B, and when t = 0.3 the point L (0.3) is 30% of the way from C to B:

 $|L(t) - C| = |\mathbf{b}| |t|$ and $|B - C| = |\mathbf{b}|$, so the value of |t| is the ratio of the distances |L(t) - C| to |B - C|.

Middle Tennessee State Heisessits

Representing Lines (5) – point normal form

 Point-normal form of a line consists of any point, R, on the line and a vector, n, perpendicular to the line.

 $\mathbf{n}\cdot(R-C)=0$

- Given B and C on the line, b = B C gives
 b → = n, which is perpendicular to
 R C. (R is any point (x, y) on the line.)
- The equation is $\mathbf{n} \cdot (\mathbf{R} \mathbf{C}) = 0$.

Changing Representations -- point normal form

- From f x + g y = 1 (implicit form) to point-normal form:
 - Example, for 2x+6y=3; (2, 6) is its normal
- From point normal form:

$$\mathbf{n} \cdot (R - C) = 0$$

to parametric form:

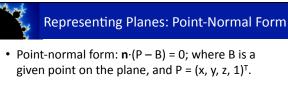

$$L(t) = C + \mathbf{n}^{\perp} \mathbf{t}$$

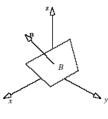

Middle Tennessee State University

Practice Question

- For a line L passes through points C(3, 4) and B(5, -2), what is the point normal form for this line?
- For a line 3x+5y=11, what is the point normal form of this line?

Middle Tennessee State University

- A plane can be infinite in 2 directions, semiinfinite, or finite.
 - Parametric form: requires 3 noncollinear points on the plane, A, B, and
 - P(s, t) = C + sa + tb, where a = A - C and b = B - C.
- $--\infty$ ≤ s ≤ ∞ and $-\infty$ ≤ t ≤ ∞: infinite plane.
- $-0 \le s \le 1$ and $0 \le t \le 1$: a finite plane, or patch.

Planes: Parametric Form (2)

· We can rewrite

$$P(s,t) = C + s\mathbf{a} + t\mathbf{b}$$

where $\mathbf{a} = A - C$ and $\mathbf{b} = B - C$, as an affine combination of points:

$$P(s, t) = s A + t B + (1 - s - t)C$$

• Compare it with the parametric form of a line:

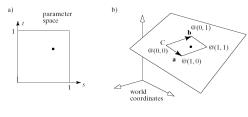

$$L(t) = tB + (1-t)A$$

Middle Tennessee State University

Planes: Parametric Form (3)

• The figure shows the available range of *s* and *t* as a square in **parameter space**, and the patch that results from this restriction in object space.

Patches

- Mapping textures onto faces involves finding a mapping from a portion of parameter space onto object space, as we shall see later.
- Each point (s, t) in parameter space corresponds to one 3D point in the patch P(s, t) = C + as + bt.
- The patch is a parallelogram whose corners correspond to the four corners of parameter space and are situated at:

P(0, 0) = C

P(1, 0) = C + a

 $P(0, 1) = C + \mathbf{b}$

P(1, 1) = C + a + b

Add the Townson Case Historia

Patches (2)

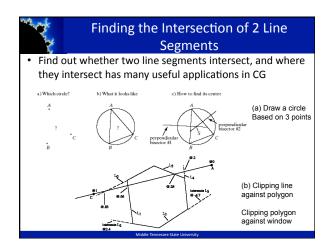

- The vectors **a** and **b** determine both the size, the shape, and the orientation of the patch.
 - If ${\bf a}$ and ${\bf b}$ are perpendicular, the grid will become rectangular.
 - If in addition a and b have the same length, the grid will become square.
- Changing *C* just translates the patch without changing its size, shape or orientation.

Andrew Transport Control (1975)

Practice Question

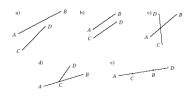

• Find **a**, **b** and **C** that create a square patch of length 4 on a side centered at the origin and parallel to the x-z plane.

Finding the Intersection of 2 Line Segments

 For two line segments, they can miss each other (a and b), overlap in one point (c and d), or even overlap over some region (e). They may or may not be parallel.

Middle Tennessee State University

Intersection of 2 Line Segments (2)

- Every line segment has a parent line, the infinite line of which it is a part. Unless two parent lines are parallel, they will intersect at some point in 2D. We locate this point.
- Using parametric representations for each of the line segments in question, call AB the segment from A to B.
 Then AB(t) = A + b t, where for convenience we define b = B A.

A CARL TOWN CASE 11-1-1-1

or

Intersection of 2 Line Segments (3)

- For two line segments AB and CD:
 AB(t) = A + bt, CD(u) = C + du
 where b = B A and d = C D.
- At the intersection, they share the single point of intersection at time t for AB, and u for CD:

$$A + \mathbf{b}t = C + d\mathbf{u}$$

$$\mathbf{b}\mathbf{t} = \mathbf{c} + \mathbf{d}\mathbf{u}$$

with $\mathbf{c} = \mathbf{C} - \mathbf{A}$.

Middle Tennessee State University

Intersection of 2 Line Segments (4)

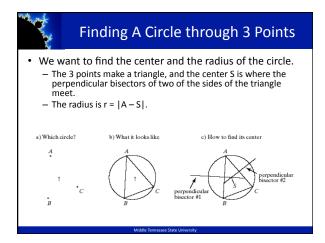

- Taking dot product with \mathbf{d}^{\perp} gives $\mathbf{b} \cdot \mathbf{d}^{\perp} \mathbf{t} = \mathbf{c} \cdot \mathbf{d}^{\perp}$.
- Taking dot product with \mathbf{b}^{\perp} gives $-\mathbf{c} \cdot \mathbf{b}^{\perp} = \mathbf{d} \cdot \mathbf{b}^{\perp} + \mathbf{u}$. $\mathbf{t} = \mathbf{c} \cdot \mathbf{d}^{\perp} / \mathbf{b} \cdot \mathbf{d}^{\perp}$ and $\mathbf{u} = -\mathbf{c} \cdot \mathbf{b}^{\perp} / \mathbf{d} \cdot \mathbf{b}^{\perp}$
- Case1: b·d[⊥] = 0 means d·b[⊥] = 0 and the lines are either the same line or parallel lines. There is no intersection.
- Case 2: $\mathbf{b} \cdot \mathbf{d}^{\perp} \neq 0$, intersect at time t for AB, u for CD
- In this case, the line segments intersect if and only if $0 \le t \le 1$ and $0 \le u \le 1$, at $P = A + b(c \cdot d^{\perp} / b \cdot d^{\perp})$.

Practice Questions

- For the following segment pairs, do they intersect? If so, when? and where?
- (1) A=(1, 4), $B=(7, \frac{1}{2})$ and $C=(\frac{7}{2}, \frac{5}{2})$, D=(7, 5)
- (2) A=(1, 4), B=(7, ½) and C(5, 0), D=(0, 7)

Middle Tennessee State University

Circle through 3 Points (2)

• The perpendicular bisector passes through the midpoint

 $M = \frac{1}{2}(A + B)$

of the line AB, in the direction $(B - A)^{\perp}$.

Let a = B - A,
 M= A + a / 2;
 direction perpendicular to AB:

• The perpendicular bisector of AB is:

 $P = A + a / 2 + a^{\perp} t$

Mark of the Control o

Circle through 3 Points (3)

– Similarly, let c = A-C,

the perpendicular bisector of AC is:

$$Q = A + c/2 + c^{\perp} u$$

(using parameter u)

 Point S lies where these two perpendicular bisectors meet, at the solution of

 $a^{\perp}t = b / 2 + c^{\perp}u$ (b = C - B, and a + b = -c).

Solve t: $t = \frac{\frac{b}{2} \cdot }{\frac{1}{2}}$

Circle through 3 Points (3)

- To find Center S:

$$S = A + \frac{a}{2} + a^{\dagger}t$$
$$= A + \frac{1}{2}(a + \frac{b \cdot c}{c \cdot a^{\dagger}}a^{\dagger})$$

- Radius R = |S - A|

$$radius = \frac{|a|}{2} \sqrt{\left(\frac{b \cdot c}{a^{\perp} \cdot c}\right)^2 + 1}$$

Middle Tennessee State University

Practice Question

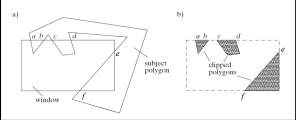

- Find the perpendicular bisector L of the segment S having endpoints A=(3, 5) and B=(9, 3)
- 2. Let the three points of a triangle equal to A=(6, 7), B=(0, -1), and C=(6, -1). Compute the center and the radius of the excircle for these three points

Middle Tennessee State Heiserits

Clipping a Polygon

• "To clip a polygon against a window" means to find which part of the polygon is inside the window and thus will be drawn.

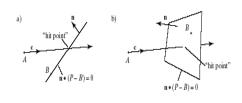

Clipping a Polygon (2)

- In Chapter 3, we looked at Cohen-Sutherland clipping of lines in a rectangular window, which involves the intersection of 2 lines.
- Here we will focus the Cyrus-Beck clipping algorithm, which clips polygons against lines and planes.

Intersections of Lines and Planes

• Intersections of a line and a line or plane are used in raytracing and 3D clipping: we want to find the "hit point".

Middle Tennessee State University

Intersections of Lines and Planes (2)

- Suppose the ray hits at $t = t_{hit}$, the **hit time**.
- At this value of t the ray and line or plane must have the same coordinates, so A + c t_{hit} must satisfy the equation of the point normal form for the line or plane, n·(P − B)= 0.
- When the ray intersects (hits) the line or plane,
 P=A + c t_{hit}, giving

$$\mathbf{n} \cdot (\mathbf{A} + \mathbf{c} \ \mathbf{t}_{hit} - \mathbf{B}) = 0.$$

 $\mathbf{t}_{hit} = \mathbf{n} \cdot (\mathbf{B} - \mathbf{A}) / \mathbf{n} \cdot \mathbf{c}, \text{ if } \mathbf{n} \cdot \mathbf{c} \neq 0.$

Middle Tonnersee State Heimstitu

Intersections of Lines and Planes (3)

• To find the hit point $P_{\rm hit}$, substitute $t_{\rm hit}$ into the representation of the ray:

$$P_{hit} = A + ct_{hit} = A + c(n \cdot (B - A)/n \cdot c).$$

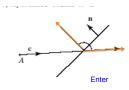

Middle Tennessee State University

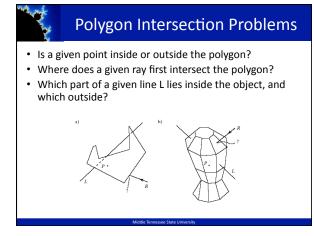

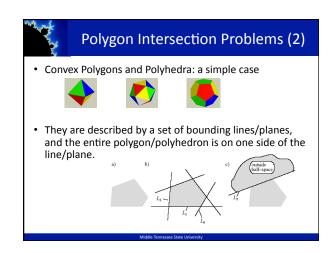

Direction of Ray

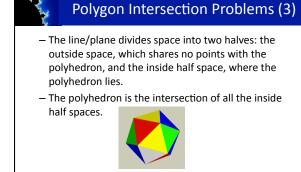

- If $\mathbf{n} \cdot \mathbf{c} = 0$, the ray is parallel to the line.
- If n·c > 0, c and n make an angle of less than 90° with each other.
- If n·c < 0, c and n make an angle of more than 90° with each other.

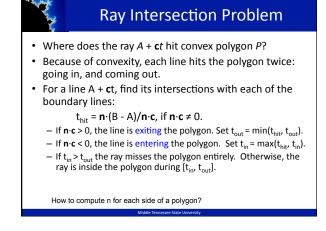

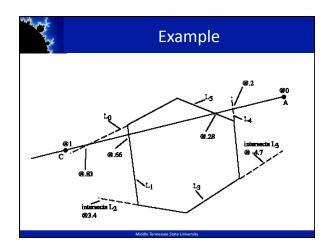

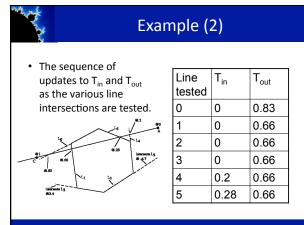

Practice Question

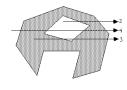

- 1. Given: A=(2, -4, 3), c=(4, 0, -4), n=(6, 9, 9), B=(-7, 2, 7), find when and where the ray A+ct hits the plane: $n \cdot (P B) = 0$
- 2. Find the point where the ray (2, 4, 2)+(-1, 4, 2)t hits the plane 3x-2y+z=0.

radio vicini

Inside-Outside Tests

 Given an arbitrary polygon, and a point P:
 How to determine whether the point P is inside or outside the polygon?

Inside-Outside Tests

- Is point P inside or outside the polygon?
 - Form a vector u = D P, where D is any point outside the polygon, and u intersects no vertices of the polygon.
 - Create n normal to u. Let w = 0 be an int
 - Let E be the vector along an edge crossed by
 u. Calculate d = E·n:
 - if d > 0,(exit polygon case), add 1 to w;
 - if d < 0, (ray enter polygon case), subtract 1 from w.
 - Repeat for each edge crossed by u. If at the end, w = 0 (even number of intersects), P is outside; else (odd number of intersects) P is inside.

Middle Tennessee State Heisessits

Inside-Outside Tests

- Is point P inside or outside the polygon?
 - Form a vector u = D P, where D is any point outside the polygon, and u intersects no vertices of the polygon.
 - Create n normal to u. Let w = 0 be an int (the winding number.)
 - Let E be the vector along an edge crossed by
 u. Calculate d = E·n:
 - if d > 0,(exit polygon case), add 1 to w;
 - if d < 0, (ray enter polygon case), subtract 1 from w
 - Repeat for each edge crossed by u. If at the end, w = 0 (even number of intersects), P is outside; else (odd number of intersects) P is inside

Edd Toron Control

Inside-Outside Tests (2)

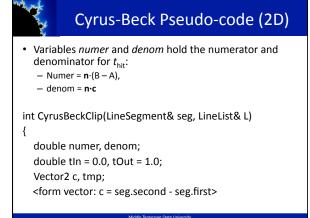

- Equivalent method: create **u** as before.
 - Calculate t_{in} , t_{out} , and t_{p} (time **u** reaches P).
 - If t_{in} ≤ t_p ≤ t_{out} , P is inside; else it is outside.

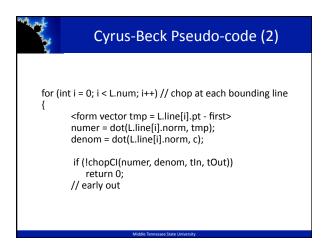

Mary Mary

Cyrus-Beck Clipping

- Cyrus-Beck clipping clips a line segment against any convex polygon P:
- int CyrusBeckClip(Line& seg, LineList& L) uses parameters seg (the line segment to be clipped, which contains the first and second endpoints named seg.first and seg.second), and the list L of bounding lines of the polygon.
- It clips seg against each line in L, and places the clipped segment back in seg. (This is why seg must be passed by reference.)
- The routine returns 0 if no part of the segment lies in P or 1 if some part of the segment does lie in P.

Middle Tennessee State Unive

Cyrus-Beck Pseudo-code (3) // adjust the endpoints of the segment; do second one 1st. // second endpoint was altered, record Max OUT time if (tOut < 1.0) { seg.second.x = seg.first.x + c.x * tOut; seg.second.y = seg.first.y + c.y * tOut; } if (tIn > 0.0) // first endpoint was altered, record Min IN time { seg.first.x = seg.first.x + c.x * tIn; seg.first.y = seg.first.y + c.y * tIn; } return 1; // some segment survives }

Cyrus-Beck Pseudo-code (4)

 The routine chopCI() uses numer and denom to calculate the hit time at which the ray hits a bounding line, determines whether the ray is entering or exiting the polygon, and chops off the piece of the candidate interval CI that is thereby found to be outside the polygon.

Cyrus-Beck Pseudo-code (5)

Address Townson Control (1975)

Cyrus-Beck Pseudo-code (6)

```
else if (denom > 0) // ray is exiting
{
   tHit = numer / denom;
   if(tHit < tIn) return 0; // early out
   if(tHit < tOut) tOut = tHit; // take smaller t
   }
   else // denom is 0: ray is parallel
   if (numer <= 0) return 0; // missed the line
   return 1; // CI is still non-empty
```

Middle Tonnersee State University

3D Cyrus-Beck Clipping

- The Cyrus Beck clipping algorithm works in three dimensions in exactly the same way.
- In 3D the edges of the window become planes defining a convex region in three dimensions, and the line segment is a line in 3D space.
- ChopCI() needs no changes at all (since it uses only the values of dot products).
- The data types in CyrusBeckClip() must of course be extended to 3D types, and when the endpoints of the line are adjusted the z-component must be adjusted as well.
